Matrices

$$\mathbf{A} = (a_{ij})_{m \times p}$$
 and $\mathbf{B} = (b_{ij})_{p \times n}$, then

$$\mathbf{AB} = (ab_{ij})_{m \times n} = \sum_{k=1}^{p} a_{ik} b_{kj}.$$

Matrix Multiplication is associative and distributive (left and right) over addition.

For square matrix \mathbf{A} , $\mathbf{A}^m \mathbf{A}^n = \mathbf{A}^{(m+n)}$

(if **A** invertible, also works for negative m, n)

$$\mathbf{A}^{\mathsf{TT}} = \mathbf{A}$$
 $(\mathbf{A} + \mathbf{B})^{\mathsf{T}} = \mathbf{A}^{\mathsf{T}} + \mathbf{B}^{\mathsf{T}}$ $(\mathbf{A}\mathbf{B})^{\mathsf{T}} = \mathbf{B}^{\mathsf{T}}\mathbf{A}^{\mathsf{T}}$

for invertible **A**, **B**:

$$\mathbf{A}\mathbf{A}^{-1} = \mathbf{I} = \mathbf{A}^{-1}\mathbf{A}$$
$$(c\mathbf{A})^{-1} = \frac{1}{c}\mathbf{A}^{-1}$$
$$(\mathbf{A}\mathbf{B})^{-1} = \mathbf{B}^{-1}\mathbf{A}^{-1}$$

Elementary Row Operations

$$\mathbf{E}_k \dots \mathbf{E}_2 \mathbf{E}_1 \mathbf{A} = \mathbf{B}$$

$$\mathbf{A} = (\mathbf{E}_k \dots \mathbf{E}_2 \mathbf{E}_1)^{-1} \mathbf{B}$$

$$\mathbf{A} = \mathbf{E}_1^{-1} \mathbf{E}_2^{-1} \dots \mathbf{E}_k^{-1} \mathbf{B}$$

Using row-reduction to find inverse:

$$(\mathbf{A} \mid \mathbf{I}) \xrightarrow{\text{Gauss-Jordan}} (\mathbf{I} \mid \mathbf{A}^{-1})$$
$$\mathbf{A}^{-1} = \mathbf{E}_k \dots \mathbf{E}_2 \mathbf{E}_1 \Rightarrow \mathbf{A} = \mathbf{E}_1^{-1} \mathbf{E}_2^{-1} \dots \mathbf{E}_k^{-1}$$

Determinants

$$A_{ij} = (-1)^{i+j} \det(\langle \text{cover row } i \text{ col } j \text{ in } \mathbf{A} \rangle)$$

$$\det(\mathbf{E}_{add}) = 1$$

$$\det(\mathbf{E}_{swap}) = -1$$

$$\det(\mathbf{E}_{mult}) = c$$

$$\det(\mathbf{A}_{\Delta}) = a_{11}a_{22} \cdots a_{nn}$$

$$\det(\mathbf{A}\mathbf{B}) = \det(\mathbf{A}) \det(\mathbf{B})$$

$$\det(c\mathbf{A}) = c^{n}\mathbf{A}$$

$$\mathbf{A} \operatorname{adj}(\mathbf{A}) = \det(\mathbf{A}) \ \mathbf{I} \Rightarrow \mathbf{A}^{-1} = \frac{1}{\det(\mathbf{A})} \operatorname{adj}(\mathbf{A})$$

$$adj(\mathbf{A}) = \begin{bmatrix} A_{11} & A_{21} & \dots & A_{n1} \\ A_{12} & A_{22} & \dots & A_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ A_{1n} & A_{2n} & \dots & A_{nn} \end{bmatrix}$$

Cramer's rule: for $\mathbf{A}\mathbf{x} = \mathbf{b}$,

$$x_n = \frac{\det(\langle \mathbf{A} : \text{replace } n\text{-th col with } \mathbf{b} \rangle)}{\det(\mathbf{A})}$$

Spaces

Space notation:

- $\{(a, a-b, 2b+c) \mid a, b, c \in \mathbb{R}\}$ (explicit)
- $\{(x, y, z) \mid x + y + z = 0\}$ (implicit)

Spans & Containment

Take
$$U := \{ \boldsymbol{u}_1, \boldsymbol{u}_2, \dots, \boldsymbol{u}_k \}$$

 $\operatorname{span}(U) = \operatorname{set} \text{ of all linear combinations of } U$
 $[\boldsymbol{u}_1 \quad \boldsymbol{u}_2 \quad \dots \quad \boldsymbol{u}_k \quad \boldsymbol{v}] \text{ consistent} \Rightarrow \boldsymbol{v} \in \operatorname{span}(U).$
 $\operatorname{ref} [\boldsymbol{u}_1 \quad \dots \quad \boldsymbol{u}_k] \text{ no zero-row} \Rightarrow \operatorname{span}(U) = \mathbb{R}^k.$
 $\operatorname{Take} V := \{\boldsymbol{v}_1, \boldsymbol{v}_2, \dots, \boldsymbol{v}_k\}$
 $\operatorname{each} \boldsymbol{u}_i \in \operatorname{span}(V) \iff \operatorname{span}(U) \subseteq \operatorname{span}(V)$

Subspaces, Linear Independence

Definition of subspace $V: \mathbf{0} \in V$, and $\forall \boldsymbol{u}, \boldsymbol{v} \in V$. $\forall c, d \in \mathbb{R}$. $c\boldsymbol{u} + d\boldsymbol{v} \in V$ U is LI means only trivial solution for $c_1\boldsymbol{u}_1 + c_2\boldsymbol{u}_2 + \cdots + c_k\boldsymbol{u}_k = \mathbf{0}$.

Basis and Coordinate systems

A set of vectors S is a basis for vector space V iff

- S is linearly independent
- S spans V

Given basis S, and $\mathbf{v} \in V$

$$oldsymbol{v} = c_1 oldsymbol{s}_1 + c_2 oldsymbol{s}_2 + \dots + c_k oldsymbol{s}_k$$

 $(oldsymbol{v})_S = (c_1, c_2, \dots, c_k) \in \mathbb{R}^k$

Coordinate Systems

 $\forall \boldsymbol{u}, \boldsymbol{v} \in V. \ \boldsymbol{u} = \boldsymbol{v} \iff (\boldsymbol{u})_S = (\boldsymbol{v})_S \text{ (uniq.)}$ $\forall \boldsymbol{u}, \boldsymbol{v} \in V.c, d \in \mathbb{R}. \ (c\boldsymbol{u} + d\boldsymbol{v})_S = c(\boldsymbol{u})_S + d(\boldsymbol{v})_S$ Let k = |S|. $\boldsymbol{v}_1, \boldsymbol{v}_2, \dots \in V, \text{ are linear independent} \iff (\boldsymbol{v}_1)_S, (\boldsymbol{v}_2)_S, \dots \in \mathbb{R}^k \text{ are linear independent.}$ $\operatorname{span}\{\boldsymbol{v}_1, \boldsymbol{v}_2, \dots\} = V \iff \operatorname{span}\{(\boldsymbol{v}_1)_S, (\boldsymbol{v}_2)_S, \dots\} = \mathbb{R}^k.$

Dimensions

 $\dim(V) := |S|$ where S is a basis for V, is unique.

- S is linearly independent
- $\operatorname{span}(S) = V$
- $|S| = \dim(V)$

2 of above true \Rightarrow all true.

Transition Matrices

S and T are bases for V, for $v \in V$.

$$\mathbf{P}_{S,T} = egin{bmatrix} [m{s}_1]_T & [m{s}_2]_T & \dots & [m{s}_k]_T \end{bmatrix}$$

is transition matrix from basis S to T. ie

$$[\mathbf{v}]_T = P_{S,T}[\mathbf{v}]_S$$
$$[\mathbf{v}]_S = P_{S,T}^{-1}[\mathbf{v}]_T$$

Rowsp and Range(Colsp)

Take $\mathbf{R} := \operatorname{ref}(\mathbf{A})$ is $m \times n$.

- Row operations preserve rowsp.
- Rows in **R** form basis for rowsp.
- Pivot columns in ${\bf R}$ correspond to linearly independent columns in ${\bf A}$

Note: row operations preserve linear (in)-dependence of columns but could destroy other information like colsp.

Column space of $\mathbf{A} = \{ \mathbf{A} \boldsymbol{u} \mid \boldsymbol{u} \in \mathbb{R}^n \}$. So $\mathbf{A} \boldsymbol{x} = \boldsymbol{b}$ consistent $\iff \boldsymbol{b} \in \operatorname{colsp}(\mathbf{A})$.

Rank Nullity

$$\operatorname{rank}(\mathbf{0}) = 0$$

$$\operatorname{rank}(\mathbf{I}_n) = n$$

$$\operatorname{rank}(\mathbf{A}) \leqslant \min\{m, n\} \qquad (\ddagger)$$

$$\operatorname{rank}(\mathbf{AB}) \leqslant \min\{\operatorname{rank}(\mathbf{A}), \operatorname{rank}(\mathbf{B})\}$$

If equality holds in (‡), **A** has **full rank**.

$$\operatorname{rank}(\mathbf{A}) = \operatorname{rank}(\mathbf{A}^{\intercal})$$

 $\operatorname{rank}(\mathbf{A}) + \operatorname{nullity}(\mathbf{A}) = \operatorname{no. columns}$

Kernel/Nullspace

$$\operatorname{null}(\mathbf{A}) := \{ \boldsymbol{u} \in \mathbb{R}^n \mid \mathbf{A}\boldsymbol{u} = \mathbf{0} \}$$

Suppose $\mathbf{A}\mathbf{v} = \mathbf{b}$, then general solution of $\mathbf{A}\mathbf{x} = \mathbf{b}$ $x \in \{u + v \mid u \in \text{null}(\mathbf{A})\}\$

Vectors

Inner product: $\mathbf{u} \cdot \mathbf{v} := \mathbf{u}^{\mathsf{T}} \mathbf{v}$

$$\|oldsymbol{u}\| = \sqrt{oldsymbol{u} \cdot oldsymbol{u}}$$
 $\|coldsymbol{u}\| = |c| \|oldsymbol{u}\|$
 $d(oldsymbol{u}, oldsymbol{v}) = \|oldsymbol{u} - oldsymbol{v}\|$
 $\cos \angle (oldsymbol{u}, oldsymbol{v}) = \frac{oldsymbol{u} \cdot oldsymbol{v}}{\|oldsymbol{u}\| \|oldsymbol{v}\|}$
 $\|oldsymbol{u} + oldsymbol{v}\| \leqslant \|oldsymbol{u}\| + \|oldsymbol{v}\|$ (\triangle ineq.)

Orthogonal

$$m{u}\cdot m{v}=0 \iff m{u}\perp m{v}$$
 orthogonal \Rightarrow linear independence. orthonormal := orthogonal \wedge norm 1. To check if S is orthogonal basis for V :

- (i) S is orthogonal
- (ii) $|S| = \dim(V)$ or span(S) = V (ref. dim)

Projections

Let S be an orthogonal basis for V, then $\forall \boldsymbol{w} \in \mathbb{R}^n$,

$$p = rac{oldsymbol{w} \cdot oldsymbol{s}_1}{oldsymbol{s}_1 \cdot oldsymbol{s}_1} oldsymbol{s}_1 + rac{oldsymbol{w} \cdot oldsymbol{s}_2}{oldsymbol{s}_2 \cdot oldsymbol{s}_2} oldsymbol{s}_2 + \dots + rac{oldsymbol{w} \cdot oldsymbol{s}_k}{oldsymbol{s}_k \cdot oldsymbol{s}_k} oldsymbol{s}_k$$

is projection of w on V. (existence of projections)

Case $w \in V$, then p = w. For orthonormal basis, simplify expr as denominator becomes 1.

Gram-Schmidt Algorithm

Basis $U := \{u_1, u_2, ..., u_k\}$ for V.

$$\boldsymbol{v}_1 = \boldsymbol{u}_1$$

for $i \in \{2, 3, \dots, k\}$

$$oldsymbol{v}_i = oldsymbol{u}_i - \sum_{j=1}^{i-1} rac{oldsymbol{u}_i \cdot oldsymbol{v}_j}{oldsymbol{v}_j \cdot oldsymbol{v}_j} \,\, oldsymbol{v}_j$$

 $\{v_1, v_2, \dots, v_k\}$ form orthogonal basis for V.

Orthogonal matrices

iff $A^{T} = A^{-1}$. rows and cols form orthonormal basis for \mathbb{R}^n .

Note: Transition matrix between two orthonormal bases is orthogonal. So $\mathbf{P}_{T,S} = (\mathbf{P}_{S,T})^{-1} = (\mathbf{P}_{S,T})^{\mathsf{T}}$

Eigenvalues

 λ is an eigenvalue of A iff $\exists v \neq 0$. $\mathbf{A}v = \lambda v$. Characteristic polynomial is $det(\mathbf{A} - \lambda \mathbf{I}) = 0$ Eigenspace $E_{\lambda} := \text{nullspace of } (\mathbf{A} - \lambda \mathbf{I}).$ To diagonalise $n \times n$ matrix **A**.

- 1. Find all distinct $\lambda_1, \lambda_2, \dots, \lambda_k$,
- 2. For each λ_i , find basis $S_{\lambda i}$ for eigenspace $E_{\lambda i}$ (If $|S_{\lambda i}| < p_i$ where p_i is power of $(\lambda - \lambda_i)$ in polynomial, then not diagonalisable, abort.)
- 3. Set $S = \bigcup_{i \in \{1,...,k\}} S_{\lambda i} = \{u_1, u_2, ..., u_n\}$ (union the eigenbases).

A is diagonalisable if |S| = n.

$$\mathbf{P} = \begin{bmatrix} \mathbf{u}_1 & \mathbf{u}_2 & \dots & \mathbf{u}_n \end{bmatrix} \text{ st. } \mathbf{A} = \mathbf{P} \mathbf{D} \mathbf{P}^{-1}.$$

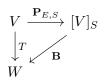

For orthogonally diagonalisable (symmetric) matrix A, Gram-Schmidt and normalise the bases in step 2, then $\mathbf{A} = \mathbf{P}\mathbf{D}\mathbf{P}^{\mathsf{T}}$.

Linear Transformations

Suppose $T: V \to W$ is a linear transformation and $S = \{ \boldsymbol{u}_1, \boldsymbol{u}_2, \dots, \boldsymbol{u}_n \}$ is a basis for V.

If T(S) is known, and $\mathbf{P}_{E,S}$ is the transition matrix from basis E to S,

$$\mathbf{B} = \begin{bmatrix} T(\boldsymbol{u}_1) & T(\boldsymbol{u}_2) & \cdots & T(\boldsymbol{u}_n) \end{bmatrix}.$$

(generalisable).

Corner case matrices

Standard non-diagonalisable matrix: $\begin{bmatrix} a & 1 \\ 0 & a \end{bmatrix}$.

$$\mathbf{A} = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}; \mathbf{B} = \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix} \text{ then}$$
$$\mathbf{A}\mathbf{B} = \mathbf{0} \text{ but } \mathbf{B}\mathbf{A} \neq \mathbf{0}$$

$$\begin{bmatrix} 1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 3 \end{bmatrix}$$

$$\mathbf{A} = \begin{bmatrix} 1 & 2 \\ 0 & -1 \end{bmatrix}; \mathbf{B} = \begin{bmatrix} 1 & 3 \\ 0 & -1 \end{bmatrix} \text{ then}$$

$$\mathbf{A}^2 = \mathbf{B}^2 = \mathbf{I} \text{ but } \mathbf{A} \neq \mathbf{B}, (\mathbf{A}\mathbf{B})^2 \neq \mathbf{I}$$

$$\mathbf{A} = \begin{bmatrix} 2 & 1 \\ 3 & 2 \end{bmatrix}; \mathbf{B} = \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}$$
then

$$(\mathbf{A}\mathbf{B})^k \neq \mathbf{A}^k \mathbf{B}^k, (\mathbf{A}\mathbf{B})^\intercal \neq \mathbf{A}^\intercal \mathbf{B}^\intercal, (\mathbf{A}\mathbf{B})^{-1} \neq \mathbf{A}^{-1} \mathbf{B}^{-1}$$

Theorem. Invertible Square Matrix

For any square matrix **A**:

A is invertible.

 \iff **A**x = 0 only has trivial solution,

 \iff rref(**A**) = **I**,

 \iff **A** = **E**_k ... **E**₂**E**₁,

 $\iff \det(\mathbf{A}) \neq 0,$

 \iff rows/cols in **A** form basis for \mathbb{R}^n ,

 \iff **A** has full rank,

 \iff 0 is not an eigenvalue of **A**.
